

Satellite EO based information for Impact Assessment

www.esa.int

European Space Agency

Some Abstract Considerations

European Space Agency

- 1. Construction of reference baseline from historical data
- 2. Monitoring impact of on-going projects
 - Environmental impact eg pollution/contamination, habitat degradatation, fragmentation, change in exposure to natural disasters (eg flood, landslide)
 - Social impact (eg displacement of locals, fragmentation of crop land, access to water etc)
- 3. Monitoring overall impact of an investment project:
 - Map changes in relevant conditions over a set of reference years to detect and assess consequences of interest (eg change in crop cover, reduction in forest conversion,
- 4. Characterisation of impact on one-off events
- 5. Conducting regular required EIAs
- 6. Remediation compliance (ie ensuring overall net lack of impact)

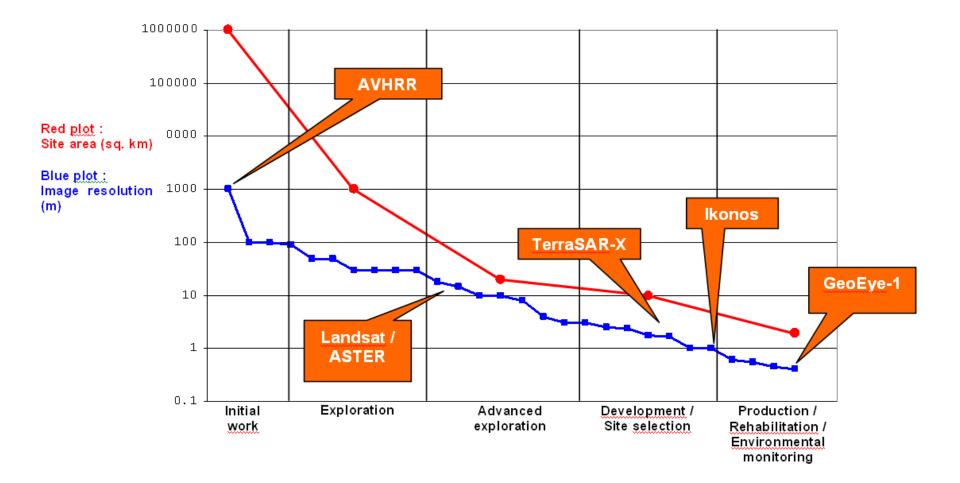

Issues to consider

- What are the indicators of interest to the stakeholders and is there a related spatial signature as a component of these indicators?
- 2. Are there measureable changes that enable construction of these indicators (case in point – consider where avoided deforestation is an indicator of interest). Do the measurable changes actually correspond to variations in the indicator being generated?
- 3. Are the changes detected actually related to the project being monitored (ie how to characterise the spatial and temporal footprint of the project being monitored)?
- 4. Spatial and temporal scales
- 5. Is there a certified process for assessing the impact of interest and is this defined in such a way that EO derived information can/cannot be used?
 European Space Agency

Mining activities – spatial scales and EO obsering resolutions

Critical enabling capabilities

- Long term archive of image data:
 - Radar imagery 1991 present
 - Optical imagery 1988 present
- Interoperable data Extraction of information independent of exact sensor acquiring imagery
- Independent validation:
 - Information extraction based on peer reviewed algorithms
 - Application of algorithms is structured as series of standard processing steps
 - Implementation performance is verified over appropriate number and types of test site under representative environmental conditions
 - Implementation approach is reproducible by independent third parties
- Acceptance as evidence

Reference Baseline

European Space Agency

- Two situations with different implications:
 - 1. Activity has already started
 - 2. Activity is still to be initiated
- For situation 1:
 - Agree reference epoch
 - Agree parameters which effectively characterise the baseline situation
 - Review availability of archived imagery/data
 - Construct reference maps (eg forest cover)/statistics/climatology (eg seasonal chlorophyll-a concentration, monthly PM10 concentration)
- For situation 2:
 - Agree area of interest and parameters which effectively characterise the baseline situation
 - Work with satellite operators to acquire all appropriate imagery data for area of interest
 - Construct reference maps

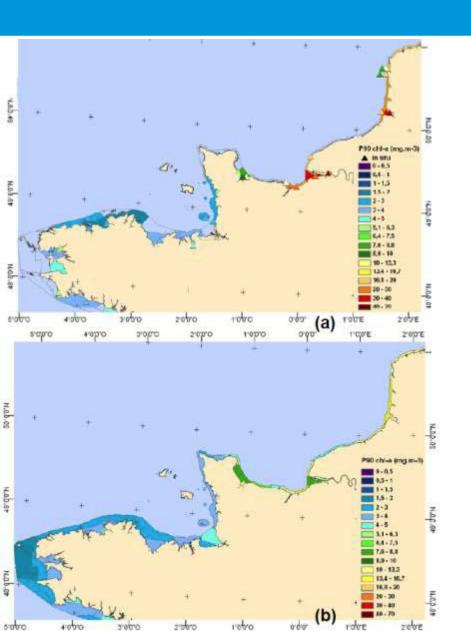

Illustrative examples

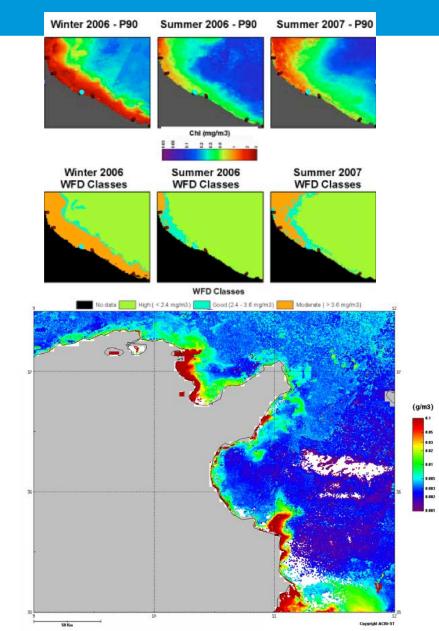

- Static information:
 - National forest cover for reference year (eg for REDD)
 - Agricultural practices prior to investment in improved irrigation
 - Forest habitat status prior to initiating mining operations
 - Coastal habitat status prior to construction of new terminal/ deployment of new aids to navigation (eg Marine Highway)
 - Distribution of houses prior to a development activity (eg dam construction, mining activity, road/rail construction)
 - Area covered by informal housing
- Process characterization
 - Coastal conditions during baseline period (eg for EU Water Framework Directive, Marine Strategy Framework Directive)
 - Statistics of occurrences of oil discharges from vessels prior to starting operational surveillance
 - Rate of change of coastline prior to remediation measures
 - Land deformation rate due to ground water extraction European Space Agency
- Exposure to natural disasters (eg flood, landslide)

Monitoring impact of on-going projects

Typical monitoring situations

- 1. Detection of changes caused by project execution
 - Habitat degradation/fragmentation
 - Surface water contamination
 - Changes in surface water distribution
 - Changes in housing distribution
 - Changes in land use practices
 - On-set of land subsidence
- 2. Impact assessment approach:
 - Dedicated data acquisition strategy matched to estimated:
 - time-scale of change
 - spatial-scale of change
 - spatial extent of change
 - Analyse changes as project progresses
 - Communicate findings with project implementation team to review monitoring approach and ensure project impacts are minimised as the project progresses

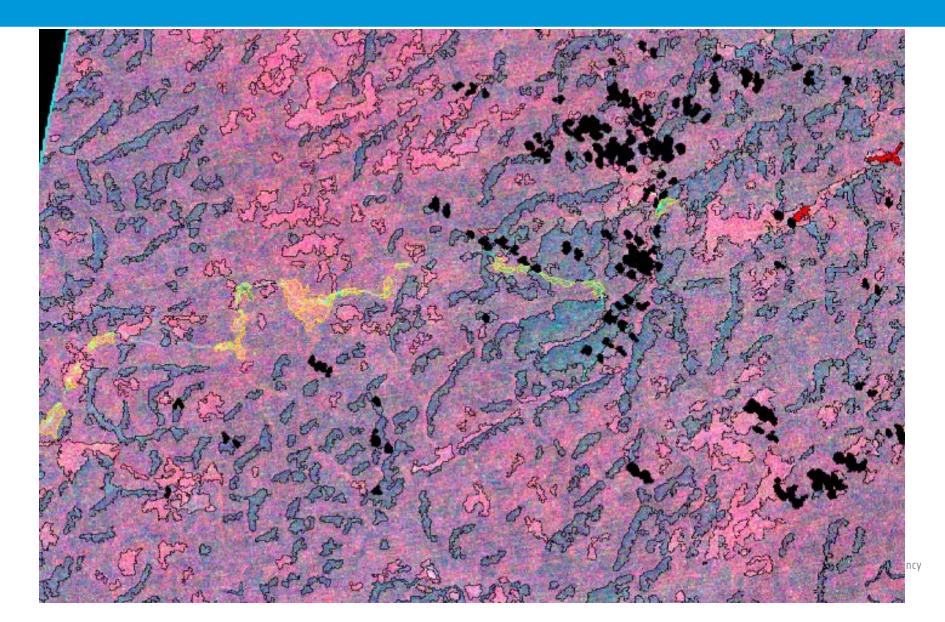

Illustrative examples

- 1. Impact of construction for SOS Children's Villages
- 2. Environmental impact of motorway construction
- 3. Environmental impact of oil sands processing on surrounding habitats
- 4. Detection of land subsidence caused by tunneling of metro lines (eg London, Barcelona)
- 5. Monitoring pollution occurrence for offshore oil and gas production concessions

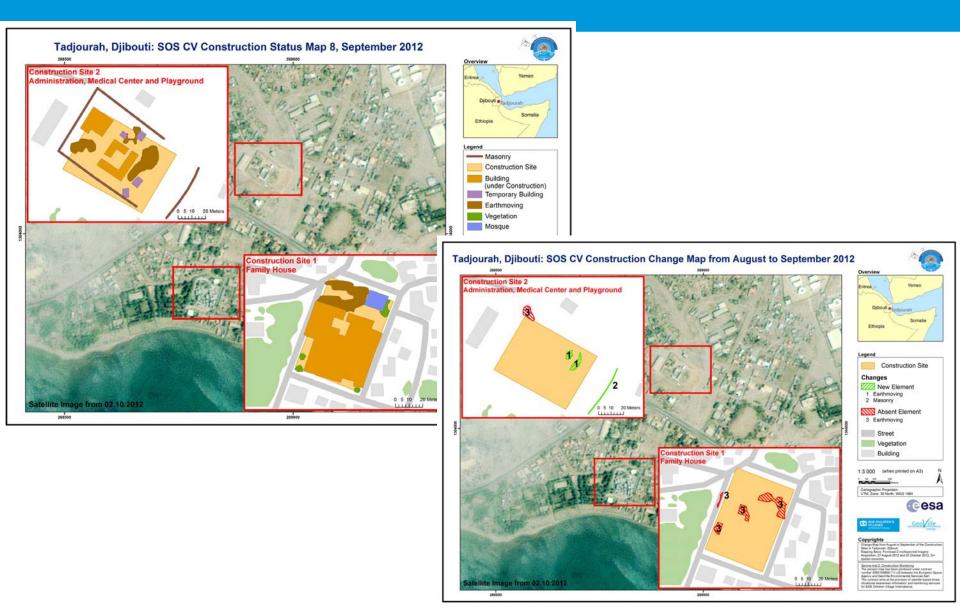

Impact of policies

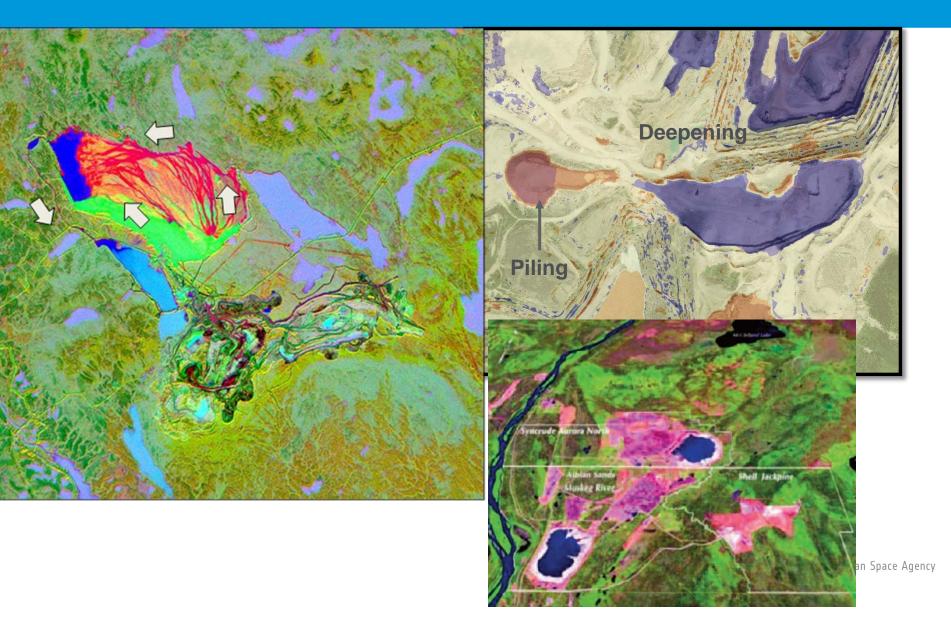

Monitoring construction activities

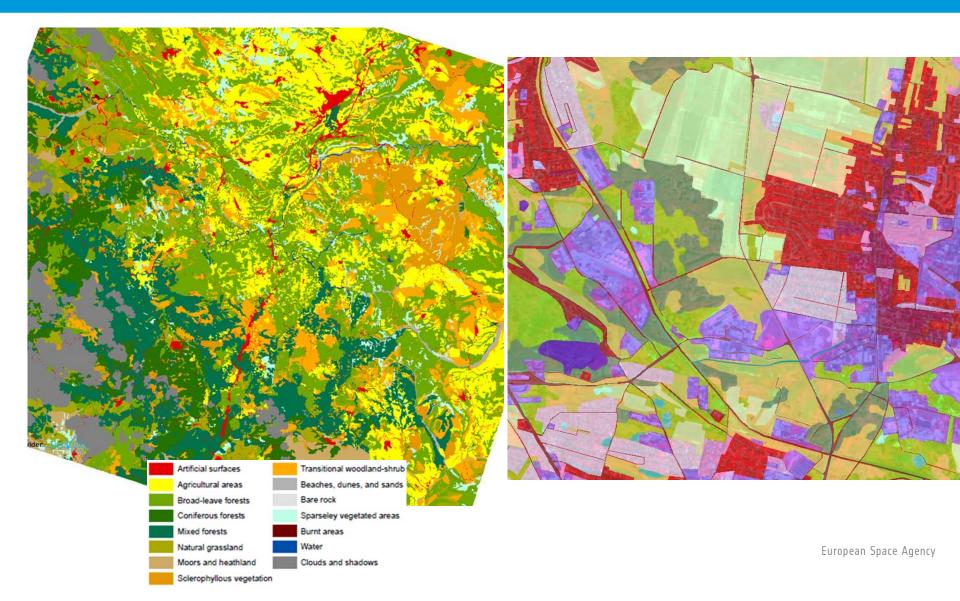

Monitoring mining impacts

Impact & progress of construction projects

Impact of tunnelling

European Space Agency

Monitoring overall impact of completed projects

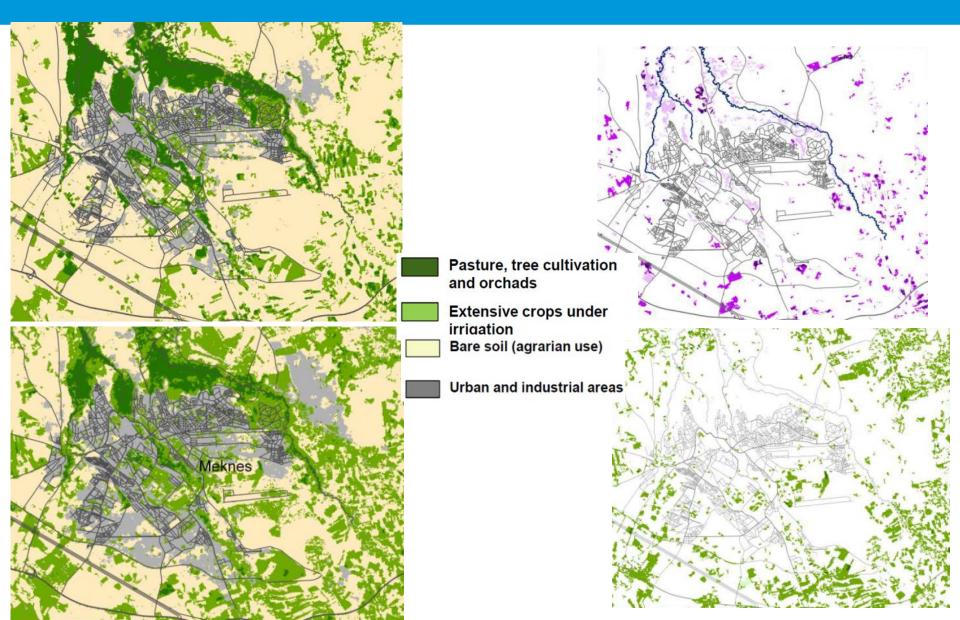

Illustrative examples

- 1. Changes in agricultural practices resulting from investment in improved irrigation in Morocco
- 2. Water quality in coastal areas resulting from improvement projects
- 3. Impacts of Palm Oil Development Project in PNG
- 4. Impact of Marine Highway implementation in West Indian Ocean with respect to contamination of coral habitats

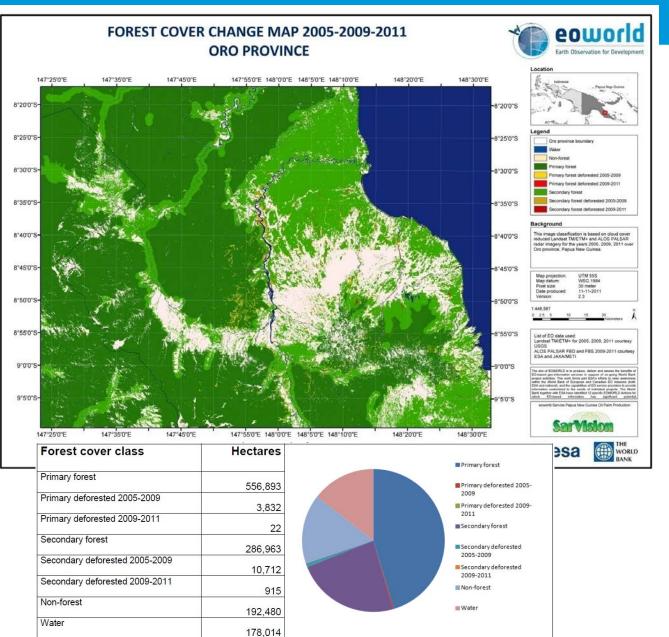

Impact of irrigation improvement

Palm oil

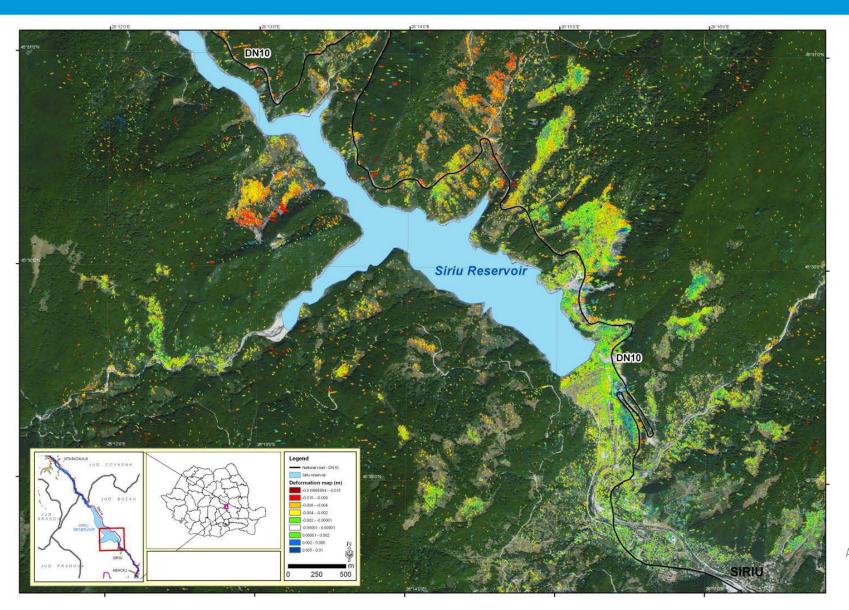

European Space Agency

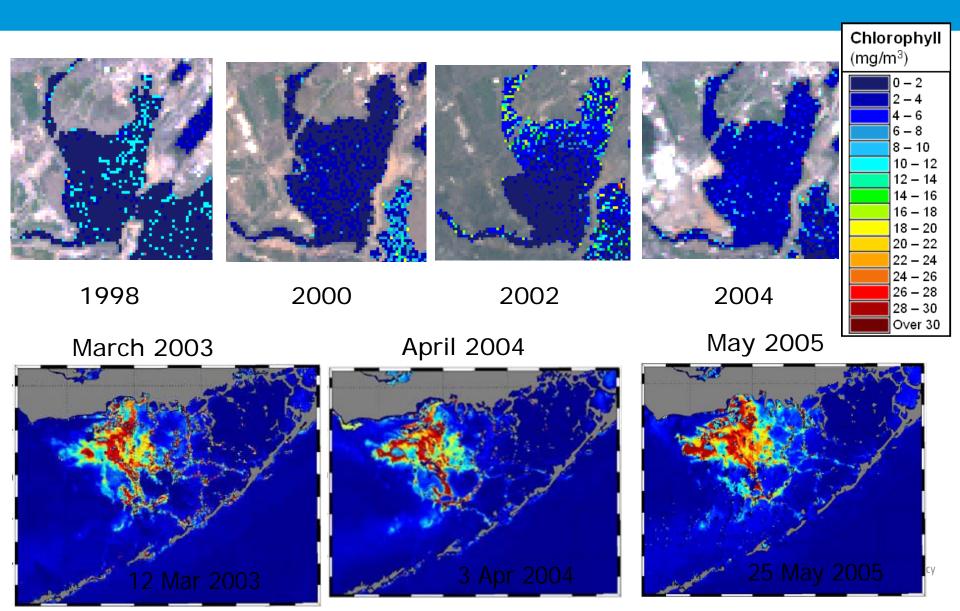

Impact of dam construction

Water quality improvement projects

Characterisation of impact of one-off events

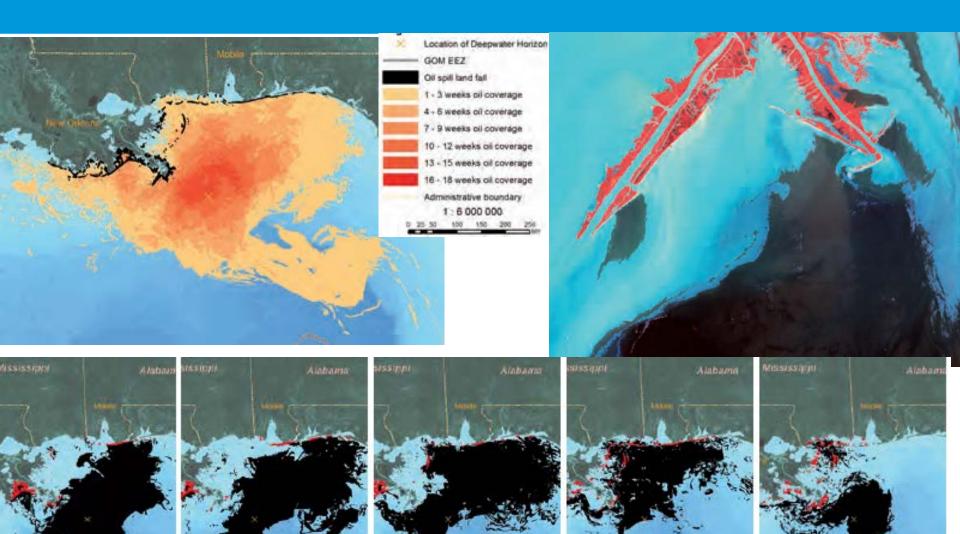

- 1. Typical situation:
 - a. Rapid characterisation of changes of interest
 - b. Lower resolution to ensure appropriate covered
 - c. Later analyses provide higher resolution, finer scale analyses
- 2. Key considerations:
 - Is there a reference baseline?
 - If not, are historic data available to support the construction o a reference baseline
 - What are the impacts to be measured
 - Have sufficient data been collected around the event to enable a credible characterisation of the consequences
- 3. Illustrative examples:
 - a. Habitat contamination from Deep Water Horizon leak
 - b. Damage assessment from flood/landslide events

Example - DWH

week 26

week 27

week 25

week 23

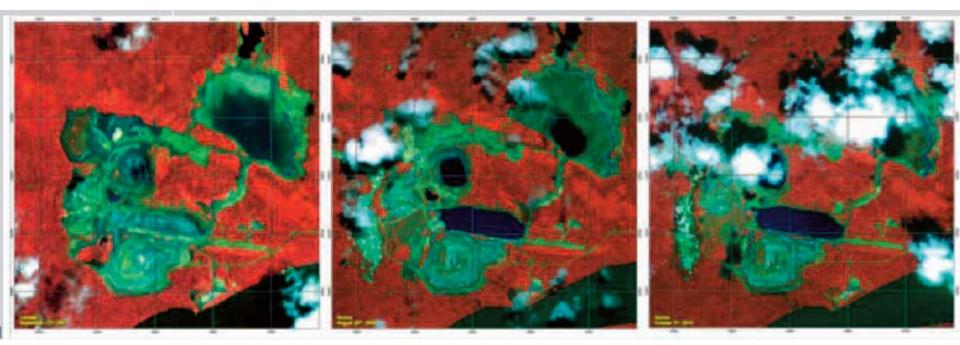

Monitoring compliance with remediation obligations

Remediation obligations

- 1. Both parties have vested interest:
 - Project implementation organistation (eg mining company) "it wasn't us"
 - Regulatory body "ensure complance"
- 2. Satellite derived information ensures independent information source

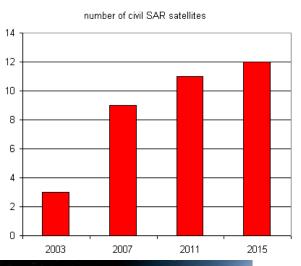

A note on the underlying technologies

Evolution in satellite observing capabilities

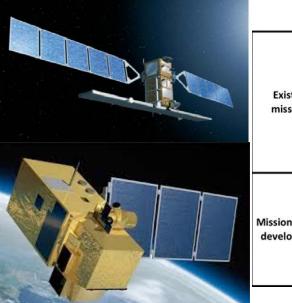

EVOLUTION IN OBSERVING PERFORMANCE

Conclusions

- EO derived information can support consistent change detection as an input to impact assessment over a wide range of
 - Time-scales
 - Spatial scales
 - Coverage
 - Environmental situations
- Where EO derived information does not provide total characterisation of the indicators of interest, it can provide important context:
 - Optimisation of in-situ data collection strategies
 - Understand spatial/temporal variations around in-situ sampling to ensure representivity or extrapolate over wider area
- Increasing number of increasingly performant satellites ensures:
 - More comprehensive archives for reference epochs
 - Opportunity to characterise changes of interest over range of spatial scales and time scales/periods
- Main issues to address:
 - Awareness of EO capabilities in support of impact assessment assessment
 - Establishment of best practice guidelines to integrate EO
