KEY ISSUES FOR SEA IN RETIREMENT OF COAL-FIRED POWER STATIONS AND ASSOCIATED MINE CLOSURES

11.1 EXISTING SEA GUIDANCE/GUIDELINES FOR RETIREMENT OF COAL-FIRED POWER STATIONS AND ASSOCIATED COAL MINE CLOSURES

An international survey of existing SEA guidelines conducted for the IAIA was unable to identify any that are specifically focused on the retirement of coal fired power stations or associated coal mines.

Similarly, no such specific EIA guidelines have been identified, although there are some for coal mining and many for mining in general\(^1\), and many sources discussing the impacts of coal mining\(^2\) and coal plants in operation\(^3\). There are also publications focusing on managing the social impacts of mine closure\(^4\). Environmental, health and safety guidelines for thermal power plants are available from the World Bank Group\(^5\).

11.2 COAL-FIRED POWER STATIONS: INSTALLED CAPACITY

China has the highest installed capacity of coal power plants in the world. As of July 2022, it operated coal plants with a combined capacity of 1,074.1 GW. This was more than four times the operational capacity of coal plants in the United States, which ranked third (Table 11.1).

According to the Global Coal Mine Tracker (GCMT)\(^6\), in July 2022, there were 7,242 operating coal mines worldwide. China has by far the largest number (3,326), followed by Indonesia (557) and the USA (538) (Table 11.2).

6 The Global Coal Mine Tracker is a worldwide dataset of coal mines and proposed projects. The most recent update – published in July 2022 – includes operating mines producing 1 million tonnes per year or more, with smaller mines included at discretion. The tracker also includes proposed coal mines and mine expansions with a designed capacity of 1 million tonnes per year or more (see: https://globalenergymonitor.org/).

11.3 BACKGROUND TO COAL ENERGY GENERATION

Retirement of CFPPs comprises two phases: shut down - when operational impacts cease; and decommissioning - the series of activities required to redevelop the site. Decommissioning will typically comprise a mixture of repurposing, demolition, removal of demolition and waste material from site, land remediation and redevelopment. In the context of the Energy Transition, both of these phases are likely to take many years to complete.

CFPPs generate electricity through a series of energy conversion stages: coal is burned in boilers to convert water to high-pressure steam, which is then used to drive a steam turbine to generate electricity. Figure 11.1 shows a generalized schematic diagram for a thermal power plant and the associated operations required to run a plant.

High-temperature, high-pressure steam is generated in the combustion plant (boiler) and then enters the steam turbine. At the other end of the steam turbine is the condenser, which is kept at a low temperature and pressure using a cooling agent, usually water. Through the steam condensing process, that cooling water is warmed. If the cooling system is an open or a once-through system, this warm water is released back to the source water body (such as a river, lake, or marine environment). In a closed system, the warm water is cooled by recirculation through cooling towers, lakes, or ponds, where the heat is released into the air through evaporation and/or sensible heat transfer before being used in the cooling process again. If a recirculating cooling system is used, only a relatively small amount of makeup water is required to offset the evaporative losses and cooling tower blowdown that must be discharged periodically to control the build-up of solids. A recirculating system uses about one twentieth the water of a once-through system.

In many countries, CFPP sites are located on the coast and use coastal sea water for cooling in once, through cooling systems (see Figure 11.2).

Coal-fired steam generation systems generally use pulverized or crushed coal. Several types of coal-fired steam generators are in use and are generally classified based on the characteristics of the

---

7 Energy transition is the change in the composition or structure of primary energy supply, from fossil-based systems to renewable energy sources and electrification. It affects the energy sector and other sectors that produce energy-related emissions, such as transportation and industry.

8 IFC (2008b)

9 Suarez and Myllyvirta (2020)
coal fed to the burners and the mode of burning the coal. The coal can be transported to the powerplant by rail, barge, or truck\(^\text{10}\), although the majority of the CFFPs in the pilot countries use sea-going barges to deliver coal to the plants.

11.4 ENVIRONMENTAL ISSUES OF OPERATIONAL COAL FIRED POWER PLANTS

11.4.1 Greenhouse gases

The burning of coal in CFPPs emits greenhouse gases (GHG)—predominately carbon dioxide (CO$_2$) with relatively minor nitrous oxide (N$_2$O) to the atmosphere, contributing significantly to climate change impacts. The volume of emissions from CFPPs is a function of the efficiency of the energy conversion of the plant and the fuel type (coal or lignite).

Table 11.33 shows the range of emission performances for a range of CFPP types.

**Table 11.3: Typical carbon dioxide emissions performance of new thermal power plants**

11.4.2 Air quality

When coal burns, the chemical bonds holding its carbon atoms in place are broken, releasing energy. However, other chemical reactions also occur, many of which carry toxic airborne pollutants and heavy metals into the environment.

This air pollution includes sulphur dioxide ($SO_2$) produced when the sulphur in coal reacts with oxygen. In turn, the $SO_2$ combines with other molecules in the atmosphere (including water vapour) to form small, acidic particulates that can penetrate human lungs. This process is linked with asthma, bronchitis, smog, and the formation of acid rain, which damages crops and ecosystems.

Nitrogen oxides ($NO_x$) are visible as smog and irritate lung tissue, exacerbate asthma, and make people more susceptible to chronic respiratory diseases such as pneumonia and influenza.

Particulate matter is the ashy gray substance in coal smoke which can cause smog and haze, and is linked to respiratory and pulmonary illnesses, such as chronic bronchitis, aggravated asthma, lung disease, cardiovascular effects such as heart attacks, and premature death.

Mercury and other toxic heavy metals result from coal combustion, can damage neurological, digestive, and immune systems, and is a serious threat to child development\(^{11}\).

Most of these emissions can be reduced by the installation of pollution control equipment (scrubbers) at the CFPPs, although many plants do not have adequate controls installed or are not monitored or maintained in line with national standards nor good international industry practice (GIIP). Table 11.4 shows the emission standards in place in various countries.

*Limits are technically in force but the regulator has delayed or failed to require compliance

Note: The table simplifies the complexity of regulation by only showing the emission limits applying to large (varyingly, >50MW to >500MW) plants. It also does not cover all exemptions either to individual plants or specific categories of plants which exist in many countries. The values are converted to 6% reference oxygen content, the most common basis used e.g. in the EU and China.

\(^{11}\) UCS (2019)
Southeast Asian coal emissions were estimated to have caused 19,880 (range 11,400–28,400) excess deaths per year in 2017\textsuperscript{12}. Pollution from the current Philippines operating fleet of CFPPs is estimated as having led to 630 deaths in 2019, as well as 1,300 new cases of child asthma, 149,000 days of work absence (sick leave) and 240 pre-term births\textsuperscript{13}. Studies show that children exposed to CFPP emissions face the highest risks, resulting in significant adverse effects on paediatric neurodevelopment, birth weight, and paediatric respiratory morbidity\textsuperscript{14}.

The quantum of pollutant emissions from CFPPs, their installed air pollution control devices, as well as population density, topography, and meteorology, play key roles in determining exposure risks\textsuperscript{15}. In general, communities living nearest to CFPPs, or those with the highest exposures, face as much as five times the risk compared with those residing farther away\textsuperscript{16}. Depending on the specific pollutants and the dominant meteorological and other atmospheric conditions, hazardous air pollutants from CFPPs can travel from 8 to 48 km from the stack unless they are deposited on the ground, chemically transformed, or removed from the air\textsuperscript{17}.

Where CFPPs are present, they contribute to ambient air pollution together with burning of other fossil fuels.

Globally, air pollution accounted for an estimated 6.67 million premature deaths in 2019 and, on average, reduces life expectancy by 1 year and 8 months (Figure 11.3), with almost 70\% of the burden of air pollution-related mortality borne by Asia\textsuperscript{18}.

\textbf{Figure 11.3: Ambient Air Pollution}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{ambient-air-pollution.png}
\caption{Ambient Air Pollution}
\end{figure}

\subsection*{11.4.3 Water quality}

Local coastal water quality can be impacted by both contaminants and increases in temperature (referred to as “thermal plume”) and from the operations of CFPPs.

Mercury is one of the key contaminants resulting from the combustion of coal in CFPPs (Table 11.5), accounting for about 13\% of global mercury emissions. Mercury is one of the most toxic elements in nature and a threat to wildlife because it accumulates and magnifies to unsafe levels in aquatic food chains (Box 11.1). After mercury is emitted into the atmosphere from the stacks of CFPPs, it settles onto both water bodies and land.

Research has shown that Asia releases a large amount of anthropogenic mercury\textsuperscript{19}. While increased burning of coal in Asia has been known to exacerbate mercury emissions and air pollution, the research estimates that Asia could produce up to 1,770 metric tons of mercury emissions per year—more than double the mercury emissions previously estimated\textsuperscript{20}.

Box 11.1: Mercury contamination of water Case Study Thailand

Mercury concentrations were found to be above safe levels in fish tissue and hair samples taken from residents near a coal-fired power plant and a paper and pulp mill in Prachinburi’s - the largest industrial area in eastern Thailand. The study concluded that the possible sources ranged from fly ash from the coal-fired power plants, coal dust from outdoor coal storage piles, ash deposits (which are spread over eucalyptus plantations in the area), as well as the possible leak of mercury-contaminated wastewater from a nearby paper and pulp mill to a public canal.

Source: Prachatai (2013)

Effluents from CFPPs include thermal discharges from the heated water emanating from the cooling systems. In some countries, where CFPPs are in coastal areas, once-through cooling systems are used that require large quantities of water that is usually drawn from the sea. Subsequently, it may be discharged at elevated temperatures, with increased brine levels and chemical contaminants (e.g., biocides, chlorine, or other additives, if used). Such discharges may affect aquatic organisms, including phytoplankton, zooplankton, fish, crustaceans, shellfish, and many other forms of aquatic life. Thermal pollution is the disturbance of water quality by elevated temperatures that cannot dissipate in a natural way and can result in significant degradation of aquatic ecosystems (Box ).

---

21 IFC (2008a)
A fleet of coal-fired power plants is situated along the Jiu River in Romania (photo). They use large volumes of water from the river for their once-through cooling systems. Here, the higher temperature of the water returned to the river was found to have a significant thermal pollution impact to the downstream aquatic ecosystems in the river.

Figure 11.4: CFPP process water inlet channel to Jiu River Romania

(Photo credit: Rosen et al. (2015))

11.4.4 Solid waste

CFPPs generate large volumes of solid wastes due to the relatively high percentage of ash in coal. This so-called bottom ash remains in the CFPP boiler bed after the coal has been combusted.

The coal combustion wastes (CCW) include fly ash (carried in the exhaust gases), bottom ash, boiler slag, and sludge. Fluidized-bed combustion (FBC) boilers generate fly ash and bottom ash, known as bed ash. Fly ash removed from exhaust gases makes up 60%–85% of the coal ash residue in pulverized-coal boilers and 20% in stoker boilers. Bottom ash includes slag and particles that are coarser and heavier than fly ash. Low-volume solid wastes from CFPPs include coal mill rejects and/or pyrites, cooling tower sludge, wastewater treatment sludge, and water treatment sludge.

The high-volume of CCW wastes is typically disposed in landfills or surface impoundments or, increasingly, may be used for a variety of beneficial purposes such as a component of concrete manufacturing. Low-volume wastes may also be disposed to landfills but are more frequently disposed in surface impoundments - sometimes at the CFPP site itself. Many CFPP owners manage their waste streams through relationships with third parties such as jointly owned waste management companies. The third parties are often landowners in the vicinity of the plant. Hazardous materials stored and used at combustion facilities include: solid, liquid, and gaseous waste-based fuels; air, water, and wastewater treatment chemicals; and equipment and facility maintenance chemicals (e.g., paint, certain types of lubricants, and cleaners).

Surface impoundments storing coal ash can fail if the integrity of the containment is compromised. This can lead to very large spills to adjacent land, and potentially to water bodies, with the potential to contaminate several hundred hectares due to the volumes of waste (Box11.3).
Inadequate management of coal ash is a known issue in some countries (Box 11.5). Due to high rainfall events and the dense population of coastal areas where the majority of CFPPs are located, solid waste storage is considered a significant environmental issue.

11.4.5 Health and safety

CFPPs are large-scale industrial facilities with a complex series of operations that have major hazards associated with materials, plants, and processes. This can lead to high numbers of workplace fatalities and injuries. The following health and safety impacts are of particular concern to workers:\footnote{IFC (2008a) annex A.}:

- Non-ionizing radiation - CFPP workers may have a higher exposure to electric and magnetic fields (EMF) than the public due to working in proximity to electric power generators, equipment, and connecting high-voltage transmission lines;
- Heat - occupational exposure to heat occurs during operation and maintenance of combustion units, pipes, and related high-temperature equipment;
- Noise - noise sources in combustion facilities include: the turbine generators and auxiliaries; boilers and auxiliaries, such as pulverizers; diesel engines; fans and ductwork; pumps; compressors; condensers; precipitators, including rappers and plate vibrators; piping and valves; motors; transformers; circuit breakers; and cooling towers;
- Confined spaces - specific areas for confined space entry may include coal ash containers, condensers, and cooling water towers;
- Electrical hazards - energized equipment and power lines can pose electrical hazards for workers at thermal power plants;
- Fire and explosion hazards - CFPPs store, transfer, and use large quantities of fuels; therefore, careful handling is necessary to mitigate fire and explosion risks. In particular, fire and explosion hazards increase as the particle size of coal is reduced. Particle sizes of coal that can fuel a propagating explosion occur within thermal dryers, cyclones, baghouses, pulverized-fuel
systems, grinding mills, and other process or conveyance equipment and at storage yards, where there is a need for regular monitoring, water sprinkling, and limitation of coal pile height;

- Chemical hazards - CFPPs utilize hazardous materials, including ammonia for NOx control systems, chlorine gas for treatment of cooling tower and boiler water and chemicals used for laboratory analyses, some of which may be classified as ozone depleting substances;
- Dust - generated in handing solid fuels, additives, and solid wastes (e.g., ash). Dust may contain silica (associated with silicosis), arsenic (skin and lung cancer), coal dust (black lung), and other potentially harmful substances;
- Operational health and safety - compared with other energy production methods, coal is significantly more dangerous than renewables and biomass as a source of energy. This is both with respect to power plants reliant on coal and the mining processes to fuel that process.  

Historically, coal has seen the greatest number of severe accidents (leading to fatalities). Example of major incidents include:

- 21 people were killed in an explosion at a coal-fired power plant in the city of Dangyang in Hubei Province, People’s Republic of China (2016);
- An explosion at a newly commissioned unit of CFPPs in northern India killed 43 people, while about 80 were injured in one of the nation’s worst industrial disasters in recent years (2017);
- Six people were injured in dust explosion and fire at a CFPP in Turkey’s Canakkale province (2018);
- A man died in an explosion at the Yallourn Power Station, Victoria, Australia (2018).

Coal (including brown coal) is responsible for over half of all deaths worldwide for all energy sources (Table 11.6).

</tbody>
</table>
| Local economy and livelihoods    | • Reduced livelihood opportunities in the host communities (less demand for food stalls, accommodation, reduced business for small retailers)  
• Increased households’ indebtedness and vulnerability to income losses related to individuals and businesses unable to repay their loans  
• Reduced revenues from renting properties and values of properties as a result of out-migration  
• Rehabilitation and redevelopment of CFPP sites will create income-generation activities |
| Gender and vulnerability         | • Women and vulnerable groups, such as the poor, persons with disabilities, children, the elderly, and indigenous communities may be disadvantaged and at particular risk  
• Incomes will be lost following closure and competition for jobs in other sectors may well increase  
• Increased competition from former male workers in CFPPs may arise in women-dominated industries (such as manufacturing and garment industries) following closure  
• Increased domestic and gender-based-violence due to loss of income and resultant stress in the household  
• Increase pressure on state welfare system.  
• Opportunities for women and vulnerable groups to acquire new skills and learn technologies.  
• Opportunities for vulnerable groups to engage in the decision-making process and in inclusive dialogue for CFPP retirement. |
| Migration and loss of local skills | • Migrants attracted to work in CFPPs and associated businesses will leave the communities.  
• Local skilled workers and skilled migrants from CFPPs will leave communities.  
• Increased vulnerability of abandoned household members whose income depends on skilled migrants.  
• Opportunities for local workers to re-skill for new opportunities in renewable energy replacement |
| Public services and infrastructure | • The early retirement of CFPP may affect public services and infrastructure directly supported by the CFPPs (e.g., health clinics, education facilities, and roads, bus, and other transportation), and through reduced tax revenues  
• Decreased public services due to less local government revenues generated from imposing taxes on CFPPs and associated businesses  
• Reduced pressure on public services and infrastructure as a result of out-migration |
| Social cohesion and engagement   | • Weakened community cohesion resulting from out-migration of community members  
• Risk of internal conflict due to increased stress as income lost  
• Opportunities of the communities to engage in the decision-making processes  
• Reduced tension between the communities, nongovernment organizations (NGOs), activists, and CFPPs |
Decommissioning activities vary widely. They range from:

- A plant being abandoned (Figure 11.6 and 11.7) with little advanced notice to workers, the surrounding community and authorities; and minimal works undertaken by the site operator or owner once operations cease;

  to

- A carefully planned redevelopment or decommissioning plans being prepared and communicated to stakeholders years ahead of shutdown, site remediation being undertaken, and future land-use opportunities realized.

Evidence suggests that there are a variety of benefits to repurposing and ensuring appropriate remediation of power plants (Figure 11.8). A report by the World Bank\(^{24}\) asserts that the direct benefits of repurposing such facilities in developing countries outweigh the costs of decommissioning. Such benefits may include land reutilization, equipment reuse (substations, generators, turbines), land remediation, and transmission and interconnection benefits. Beyond direct cost-benefits from decommissioning, repurposing plants provides social and grid stability benefits. There is a wide range of technology options available for repurposing (Table 11.8), e.g., solar PV (located on surface impoundments), concentrated solar power, biomass, battery energy storage systems, offshore wind and synchronous condensers. The options selected require careful consideration of multiple factors including renewable energy, requirements of the power systems and location. Repurposing allows for retaining part of the workforce for an upcoming repurposing project at the same site. This would partly ameliorate the socio-economic impact of potential layoffs. The repurposed plant would also continue to support local economies and the surrounding communities by providing jobs and enabling economic activities and their well-being in the long run.\(^{25}\)

One controversial repurposing technology, proposed by Japan, is to use ammonia as a fuel with coal for power generation. But there are concerns about this technology. It may be more costly as most ammonia today is produced from fossil fuels; and emissions of nitrous oxide from the combustion process may result in a global warming potential significantly much larger than even gas-fired power plants.\(^{26}\)

Conversely, poorly planned shut down and abandoned CFPPs leave a significant legacy of environmental and social impacts which are discussed in the following sections.
11.5.1 Environmental Impacts of retiring coal-fired power plants

**Greenhouse gases**

A major benefit of the closure of CFPPs will be the elimination of associated GHG emissions. However, there will still be relatively minor short-term GHG emissions from vehicles and mobile plant used during decommissioning activities.

**Air quality**

The closure of CFPPs will result in the elimination of all chimney stack emissions arising from the burning of coal. Air quality impacts from dust related to decommissioning activities will vary depending on how these activities are planned and executed. If the decommissioning of sites is not undertaken according to national and good international practice, coal ash dust from storage at CFPP sites may be an ongoing issue for local communities living in proximity (see also section below on land contamination).

**Water quality**

The closure of CFPPs will result in ending: (i) direct thermal emissions from the discharge of cooling waters to source water bodies, (ii) indirect impacts from contaminated dust in air emissions settling into water bodies in the vicinity of the plants and iii) groundwater contamination from ponds and leaks27.

Water quality impacts related to decommissioning activities will vary depending on how these activities are planned and executed. If the decommissioning of sites is not undertaken according to national and good international industry practice (GIIP), coal ash waste may contaminate nearby water bodies leading to ongoing issues for local communities living in proximity (see also section below on land contamination).

**Solid waste**

The closure of CFPPs will stop large volumes of waste (e.g., coal ash) being generated from operations, providing a long-term benefit. However, existing fly ash stored in surface impoundments is potentially a significant environmental issue if adequate provisions are not included in the CFPP decommissioning scope of work.

Ownership of surface impoundments is frequently shared between the CFPP and other parties. If waste is left in unremediated impoundments, there will be a significant environmental risk and liability issue, deterring redevelopment of land by future owners (see also section below on land contamination).

The decommissioning phase of CFPPs will generate potentially large volumes of new waste types, both hazardous and non-hazardous—particularly if a CFPP site is demolished rather than repurposed. Waste from CFPPs can potentially have a cumulative impact. Where existing local landfills have limited capacity, they will be constrained to handle additional waste from decommissioning CFPPs, and there will be a risk of illegal dumping.

**Land contamination**

Coal ash generated by CFPPs can contain heavy metal contaminants such as mercury, cadmium, and arsenic. As described in the preceding section, this material is stored in either landfill or surface impoundments. Without proper management of ash ponds, the contaminants can be released to pollute soil, ground water, drinking water and waterways28.(see Box 11.4).

---

27 https://www.ucsusa.org/resources/coal-and-water-pollution
(e.g. Box 11.5).28 USEPA (undated)
Additional hazardous materials stored and used at CFPPs include solid and liquid fuels; chemicals used for treating air, water, and wastewater; and chemicals used for equipment and facility maintenance (e.g., paints, lubricants, and cleaners). If there is poor practice in the storage and use of such hazardous materials during operations or if they are not removed from the site and properly disposed, there is a risk that they may contaminate soil and groundwater at the site. The decommissioning of CFPPs should include a site assessment and remediation plan covering potential contaminated land issues, to avoid leaving a legacy of contamination issues that will have long-term impacts on local communities and ecosystems.

11.5.2 Socio-economic Impacts of retiring coal-fired power plants

The impacts of CFPP retirement depends on the type of CFPPs. The latter, include stand-alone CFPPs (with coal supplied from elsewhere) and mine-mouth CFPPs where coal is supplied on-site. Regardless of the impacts from supply chains, stand-alone CFPPs tend to create less complicated adverse impacts compared to mine-mouth CFPPs. Socio-economic impacts can be contingent upon the age of the CFPPs as well as the project company’s corporate reputation and relationship with the communities. A range of “true costs” are associated with the extraction and use of coal\(^{29}\). These range from the costs of health effects to atmospheric pollution. Consideration of externalities such as those related to water, air pollution, land use and others can maximize environmental conservation, protect human health, and contribute to long-term stability\(^{30}\). Additionally, companies may require a significant reserve fund for decommissioning costs at a time when plant revenues may be decreasing due to closure.

---

\(^{29}\) True cost economics is most often applied to the production of commodities and represents the difference between the market price of a commodity and total societal cost of that commodity, such as how it may negatively affect the environment or public health (negative externalities). See more about true costs at https://truecostsinitiative.org/mission-vision/truecosts/.

\(^{30}\) Roth and Lawrence (2004; Schmidt et al. (2015)
Coal

Country, regional, and global economy

At the country and regional levels, specific economic structures and their complex interactions with the energy system vary greatly. Energy transition would bring substantial regional economy benefits and contribute to a country’s gross domestic product (GDP). Retiring or closing CFPPs have been reviewed positively in terms of tackling the climate crisis and the need to divest from fossil fuels in the energy supply mix in regions where coal is an anchor industry. However, these costs may be too high for some national governments to assume and will require external funding from international lenders or other funding sources to finance the retirement costs.

The retirement of CFPPs is likely to pose challenges for local and national economies that have developed a dependency on CFPPs and for the industry’s supply chains (e.g. Box 11.5). The closure of CFPPs may also cause import and export and trade imbalances between countries and regions.

Box 11.5: Potential economic impacts of retiring CFPPs in Indonesia

The Philippines’ CFPPs import coal from Indonesia and Australia and their closure could affect Indonesia’s coal export economy. The Indonesian electricity sector is dominated by CFPPs. In 2021, they contributed at least 5.5% to the total GDP. The potential impacts of retiring CFPPs includes regional job losses, losses for associated business activities along the coal supply chains, a rise in electricity tariffs, and increasing commodity and food prices. State revenues, from both corporate and salary taxes, could be reduced and thus decrease public funding and budgets for specific regions and provinces which host many CFPPs. The reduction of electricity supply without replacement sources being available may also adversely affect the operation of major economic hubs or centres, including shopping malls and factories, which consume more electricity than other industries. At least four million enterprises in Indonesia rely on the state electricity company (PLN). Without proper mitigation measures, the effort to retire CFPPs would cause adverse impacts on the national economy and intra-country trade (both energy and non-energy) in Southeast Asia.

However, the impact of retiring CFPPs is heavily dependent on the share of coal in each market’s electricity mix, the availability of sources to replace coal, and the growth rate of the electricity demand. Retiring CFPPs might increase the price of electricity (even making it unaffordable for some people), exacerbate ongoing energy supply shortages, and make it difficult to meet the ever-increasing demand for electricity in Southeast Asia that is a consequence of population growth. Without policies addressing long-term impacts in place, the rapid transition from CFPPs to renewable energy could face long-term energy supply issues. Government policies need to consider which energy source(s) might replace coal in the short, medium, and long term.

Local economy and livelihoods

In localities where the economy and livelihoods of host communities are highly dependent on the operation of CFPPs, their retirement will have both direct and indirect sociocultural and commercial consequences and could lead to socioeconomic deprivation for decades. According to the International Energy Agency, the closure of CFPPs can have adverse socio-economic consequences and unintended distributional effects due to their highly focused value chains. In most parts of the world, CFPPs can act as an anchor industry for the local area and for the livelihoods and economic development of surrounding communities. In some cases, employment at these facilities may be multi-generational.

34 Badan Pusat Statistik (undated).
35 IEA (2021b)
36 GRICCE (2019)
37 Financial Times (2018)
38 IEA (2021Bb)
As the CFPPs are set to retire, the associated business activities (e.g., food stalls, accommodation and renting services, retailers, small enterprises, food services, and transportation and social services) can be disrupted due to out-migration. This was the case in communities dominated by CFPPs in Scotland\(^\text{39}\) and the US (in the 1970s)\(^\text{40}\). Income from the related businesses will be reduced, increasing households’ indebtedness and vulnerability to poverty. However, there are opportunities when the CFPPs and the adjacent areas are rehabilitated and redeveloped as recreational areas with new income-generating opportunities.

**Legacy of socio-economic issues (crosscutting)**

CFPPs could have been established several years or even decades before environmental and social regulations were introduced and enforced. Those CFPPs might not meet regulatory requirements, such as addressing and managing impacts (usually these would be identified by environmental and social impact assessments) and mitigating the adverse impacts of developing and operating the power plants. Where there has been no regulatory monitoring and external audits, some of the outstanding issues (e.g., regarding workers and communities’ rights, socioeconomic and environmental concerns, availability of a functioning grievance mechanism) may not have been addressed; and particularly not in line with good international industrial practices, typified by the IFC Performance Standards\(^\text{41}\) and the World Bank’s environmental health and safety guidelines\(^\text{42}\).

Coal-fired electricity generation is an industry that has long been associated with human rights and environmental issues arising during the different phases of projects, including construction, operation, and decommissioning\(^\text{43}\). Disengagement from CFPPs can severely impact workers, families, and local communities that host CFPPs. Such local communities, dependent on CFPPs, may have little or no access to safety nets and social protection. Some companies do not sign everyone up to social protection schemes systematically. Some countries have relatively new social protection legislation (e.g., Philippines\(^\text{44}\) and Indonesia\(^\text{45}\)).

Where there are outstanding inequalities and disparities resulting from poor attention to and management of socioeconomic issues (e.g., lack of compensation for land and property loss, lost livelihoods and income, infringement of rights to land and associated conflict, unmet commitments for livelihood restoration entitlements) linked to CFPPs that have not been dealt with or mitigated, the retirement of such CFPPs could exacerbate those problems\(^\text{46}\).

Experience from the rest of the world, especially in Colombia\(^\text{47}\) illustrates this problem when stand-alone and mine-mouth CFPPs have been closed, leaving behind unresolved issues, including human rights violations in host communities. In Indonesia, since 2016, the communities in Winong village have blamed the Cilacap plant and its Jakarta-based operator for polluting their air and depleting the water table. The company did not deal with such issues until early 2019\(^\text{48}\).

**Employment and labour conditions**

The transition to low-carbon economies based on accessing renewable energy will change the occupational and skills pattern in the energy sector, with both job losses and gains\(^\text{49}\). The transition can create jobs in the renewable energy sector, but it will also reduce jobs in the non-renewable energy sector. There will be displacement and substitution of jobs from one sector to the other. As shown in

In addition to losing employment (when CFPPs are retired) and wages (which would be spent in the local economy), not all workers will have the skills or experience required to work in the renewable sector. The location of renewable energy development may in some cases be at or close to CFPP retirement sites. In other cases, they may be in other parts of the country, changing settlement patterns based on access to job opportunities.

The scale of job losses will vary from one plant to another, depending on their megawatt capacity. The larger the capacity of CFPPs, the more potential for job losses. It is evident that significant job losses are resulting from the global trend to replace CFPPs with renewable energy, a result of the international pledge to reduce carbon emission (under the Paris Agreement\textsuperscript{50}). For example, in Poland, the employment rate in the sector declined rapidly from 1990 to mid-2015\textsuperscript{51}. Indonesia’s electricity and gas sector employed at least 0.284 million workers\textsuperscript{52} in 2021, excluding jobs associated with the electricity infrastructure. If a number of CFPPs in Indonesia were to be closed around the same time without a proper mitigation plan, a very large number of direct jobs could be lost.

In countries where national regulatory enforcement is weak, CFPPs might have practiced substandard labour management. For instance, in Mexico between 2012 and 2013, it was found that some CFPPs illegally employed minors\textsuperscript{53}. In China, researchers reported that from 2017 to 2019, workers in CFPPs worked in hazardous, unsafe, and unhealthy environments\textsuperscript{54}. In some cases, the closure of CFPPs would abolish substandard labour and working conditions and labour exploitation. Lenders and financial institutions could require that labour and working conditions in CFPPs be improved before financing the decommissioning of such assets.

In countries where governments have not established transition measures, this could result in the coal industry not addressing injustices or equity implications for the workers or for households adapting to different energy sources and prices\textsuperscript{55}. Therefore, it is important that as part of the closure of CFPPs, opportunities are created for worker retraining (e.g., to work in the renewable energy or other sectors), and measures are taken to guarantee worker compensation and relocation support for unemployed former CFPP workers, as required by international financial institutions and national regulations.

\textsuperscript{55} Piggot et al. (2019)
Health and safety

The closure of CFPPs will end on-site occupational hazards described in sub-section on health and safety in section 11.4.1, with a consequent reduction in severe accidents and fatalities to workers on-site. There will be limited short-term health and safety issues for those workers involved in decommissioning activities. However, these are unlikely to be significant if the process is well-planned and delivered.

The decommissioning phase of CFPPs, if not undertaken to good international industry practice (GIIP), may leave hazardous waste on the site (as described in the sub-sections above on solid waste and land contamination), which could contaminate drinking water, food, and local fisheries, and cause long-term health impacts.

The World Bank’s Environmental, Health and Safety (EHS) Guidelines provide standard requirements for coal processing power plants. They outline key health and safety risks and management of health issues related to air emissions, wastewater, hazardous materials, wastes, and noise as well as issues concerning occupational and community health and safety in the life cycle of coal mines. IFC Performance Standard (PS) 2 also highlights the key labour and working conditions requirements that CFPPs should comply with. These include the International Labour Organization (ILO) labour conventions for, among other issues, rights of workers, forced labour and child labour. The Guidelines and PS can be adopted by private investors and companies for activities that are not IFC or World Bank-financed in situations where national regulatory requirements are lower than international standards.

If closure and the remediation of land are not planned carefully, there is a risk of community exposure to hazardous waste, contaminated land and open ponds, leading to disease and possible food insecurity. This was experienced in the US when a coal power plant that operated for 40 years was reported to have left behind 9.6 million tons of toxic waste.

The closure of CFPPs is both a leading requirement for the global climate change narrative and for the public health of local communities proximate to where they operate. CFPPs produce sulphur dioxide (SO₂), nitrogen oxides (NOx) and invisible particulate matter (known as PM₁₀ or PM₂.₅), which are all harmful pollutants and can contribute to chronic health conditions such as asthma and lung diseases. Children and elderly groups are particularly vulnerable to health impacts, and therefore may disproportionately benefit in the long-term from the closure of CFPPs.

A Government of Canada website for the Powering Past Coal Alliance identifies air pollution impacts from burning coal include smog, asthma, respiratory diseases, and premature deaths. The website indicates that there are massive health care and economic costs due to lost worker productivity. It also states that a recent analysis found that more than 800,000 people around the world die each year from the pollution generated by burning coal. A phase out of coal will mean real improvements in air quality and human health.

As mentioned in the section on public services and infrastructure, the closure of the CFPPs may reduce financial support to community health systems and facilities provided by their operating companies, possibly through their corporate social responsibility funding. Noise pollution and dust from CFPPs are common community complaints. Some communities may therefore welcome the ending of such impacts as a result of CFPP early retirement.
Migration and loss of local skills

CFPPs should normally invest in developing local skills and capacities to support their functioning. However, migrant workers from other places are also often employed, bringing their skills to the host communities. Some of these migrant workers will have settled permanently in communities around CFPPs, adding to their social capital. As CFPPs are retired, skilled local and migrant workers may leave host communities to seek employment elsewhere and in other sectors. In the UK, depending on the plant’s size, a coal power station typically employs around 100–500 workers directly with a similar number of people employed on a contractual basis. In the US, in 1997, a 300-MW CFPP would typically employ 54 people in operation and maintenance on an ongoing basis.63

Migrant workers and local workers trained by the CFPPs could leave their families behind or move with their families for long-term employment in other places. Social networks, skills concentration, demands for vocational know-how would be affected by such migration.

Retraining opportunities may arise from efforts to retire CFPPs. Lenders and national regulatory institutions/bodies (such as ministries responsible for manpower or labour and employment) could require the CFPPs to compensate the workers affected by the closures and to offer a reskilling and upskilling programme to equip them for job opportunities in the renewable energy and other sectors. A well developed and implemented retrenchment plan can support such transition.

Indigenous communities

Indigenous peoples’ communities may be more vulnerable to the adverse impacts associated with retirement of CFPPs, e.g., through loss of identity, culture, and natural resource-based livelihoods; as well as exposure to impoverishment and diseases.64 In many countries, CFPPs are located in semi-urban and coastal areas and in remote areas where indigenous communities reside. There are documented instances of indigenous communities resisting CFPP establishment (e.g., in West Papua, Indonesia65), or being required to give up land for CFPPs in exchange for jobs, associated business activities, and community development.

The experience of indigenous peoples in the southwestern US provides useful lessons regarding CFPP closures. The Native American peoples’ lands of this region are home to large coal reserves, coal mining and coal plants. Many Native American reserves are in remote territories with high rates of unemployment and poverty. According to IEEFA66, the residing indigenous population is disproportionately impacted by environmental and health hazards associated with the coal industry. To date, communities including the Navajo Nation and Hopi Tribe have seen the loss of hundreds of high-paying power plant and mining jobs and millions of dollars in revenue, following the closure, in 2019, of the Navajo Generating Station near Page and the Kayenta coal mine that supplied it since the 1970s. In the face of CFPP closures, indigenous people communities risk losing access to ancestral land (due to redevelopment of the CFPP sites) that may play an integral role in their way of life, providing subsistence and income, plus a spiritual, sacred landscape that contributes to individual and collective identities.

CFPP closure can also provide several benefits for indigenous communities. The transition to cleaner energy sources can end or offset negative environmental and health conditions. Often, geographic isolation and historical dispossession of ancestral lands makes energy access among indigenous groups particularly difficult, encouraging the use of highly polluting biomass and biofuels. The closure of CFPPs and coal mines, and a move toward clean energy, may help to undo long-standing trends that trap indigenous peoples in an unsustainable and damaging cycle of energy inequality.67

63 See: Global Energy Monitor (undated)
64 IFC (2012b)
65 Asia Pacific Solidarity Network (2020)
66 IEEFA (2021)
Gender and vulnerability

CFPP closures may have gender specific impacts. Gender often intersects with age, disability, income, race and/or class and indigenous status to compound social inequalities. In the context of Southeast Asia, vulnerability to the transition away from coal is ever more pervasive in rural areas, especially when women and girls (particularly indigenous women) are disproportionately impacted due to their relative isolation and more entrenched traditional gender roles. These impacts can take the form of:

- Greater gender inequality in workforce demographics and wage equality;
- Increased social, health access and personal safety issues for women and girls;
- Education and health disadvantages that are acutely gendered;
- Where land is customarily owned by women, post-closure land distribution or withholding of customary land by the state as part of energy transitions can snatch these rights from women, and thus further diminish their economic, social, and cultural status.

While CFPP closure may result in direct job losses for both men and women, women are likely to feel the increased burden of social care and domestic responsibilities and can be forced to take on more (often insecure and exploitative) paid work to support families—shouldering what is known as the “triple burden.” Loss of livelihoods among male workers can prompt a shift in traditional gender roles at the household and societal level, heightening instances of intra-household tension, sexual and gender-based violence, and psychological distress. In pursuit of more secure economic opportunities, male workers impacted by closure may look to migrate out of affected communities and/or gain entry to so-called women-dominated sectors (i.e., garment factories), increasing competition that will seek only to heighten existing gendered disparities within the workforce.

Public services and infrastructure

The early retirement of CFPPs may also affect public services and infrastructure such as transportation, health, and education facilities. Retirement will reduce dust, air, and noise pollution, leading to improved public health. However, overall community health may deteriorate as support to health facilities and other services (e.g., education facilities, roads, bus, and other transportation) from CFPPs and associated businesses (including through tax revenue generation) is reduced or eliminated. Local communities reliant on a CFPP may also lose charitable contributions:

- Local community members impacted by a plant’s closing are often most in need of the services of local charities, but the charities themselves may lose a major source of contributions - based on money donated by both the plant and the plant’s wage-earning employees and the employees’ contributions of time.
- However, pressure on the public services and infrastructure could also be reduced as a result of out-migration of workers and their families.
- Local communities are often tied to the local services provided by CFPPs (Box), and so will be impacted when education or health facilities are downsized or stagnate following CFPP closure.

In countries which supply coal to many neighbouring countries (e.g. Indonesia), the closing of CFPPs can create more complex and serious problems than in developed countries.
Box 11.6: Community Dependence on Coal-Fired Power Plants and Coal Mines in Betul District, Madhya Pradesh, India

Betul District in Madhya Pradesh, India, experienced a boom in business and public infrastructure in the 1960s with the development of both coal-fired power plants and coal mines. Housing and community facilities grew, including schools, hospitals, roads, and banks. The coal industry also financed schools and medical services. It set up schools primarily for the children of its regular employees. There was a hospital only accessible to employees and dependents of the Satpura Thermal Power Station, while the rest of the community travelled to the district hospital at Betul. The communities became reliant on the facilities financed by the coal industry. Indeed, communities emerged as power plants were developed as their socioeconomic centres.

*Source: Gupta (2021)*

### Community cohesion and engagement

In some cases, the existence of particular CFPPs has been a long-standing issue of contention for local communities, often raising tensions between community members, activists, environmental NGOs, and the CFPP companies and government. In the Philippines, the anti-coal power plant movement has been growing significantly. Filipino environmental NGOs such as Greenpeace, as well as trade unions, have actively advocated against new CFPPs. In Central Java, Indonesia, communities have staged protests against long-running air pollution problems caused by ash from a CFPP. Stakeholder dialogue and citizen engagement (including with community representatives, CSO and trade union representatives) can provide meaningful mechanisms for addressing the concerns of coal industry workers, and for wider community members dependent on CFPP activity.

CFPP closure can have a negative impact on community cohesion and increase the risk of conflict within affected communities from groups of people who lose their jobs and incomes earlier compared to those who lose them later, and between groups of people who adapt more quickly and those who adapt more slowly. Being non-discriminatory regarding who loses jobs and when can help prevent conflict among worker groups, which may manifest further into the community.

| GHG emissions                | • Reduction in GHG emissions from stopping operating plant and pit, and shaft closure reducing methane emissions from coal seams  
• Uncontrolled mine abandonment may leave a legacy of methane leaks from open shafts, boreholes, fissures, and pits  |
| Water quality                | • Improved water quality following stopping dewatering (pumping water from mine) and land disturbance (tailings dams, etc.) / sediment runoff  
• Conversely, uncontrolled mine abandonment can leave a legacy of contamination on-site (e.g., old heaps, chemicals, etc.), which can contaminate downstream rivers, surface water bodies and groundwater  
• Spills and leaks (from vehicles and their cargoes) during closing of mine site can pollute groundwater and surface water  |
| Water use                    | • Closing coal mines reduces water demand for use at the coal mine  |
| Noise                        | • Long-term elimination of mine noise following closure/decommissioning  
• Short-term impacts from vehicles on-site and using local roads during decommissioning—impact on local communities  |
| Contaminated land and groundwater | • Discharges from abandoned mines—as consequence of groundwater rebound, commonly acidic, and may contain high concentrations of heavy metals  
• Contamination of land and groundwater from abandoned mines due to undisposed chemicals, hazardous materials, mine dumps, and tailings  |
| Air quality                  | • Stopping operations will reduce emissions of dust and particulate matter, NOx and SOx, but mine decommissioning activities may cause a short-term increase in such emissions  
• Fires may occur with uncontrolled mine abandonment, leading to increases in particulates  |
| Waste                        | • Redundant infrastructure, equipment, and hazardous substances can contaminate soil groundwater and surface water  
• Improper disposal of potentially toxic overburden can cause land and water contamination  |
| Land-use change              | • Impacts related to future development. Sites that have managed decommissioning and carried out land-use planning can provide significant ecological benefits through revegetation and reinstatement of ecosystems services  
• Conversely, abandoned mine sites may render the site as a liability  |
| Land degradation             | • Slumpage from collapse of underground works may make the site unsuitable for other uses  
• Failure of mine walls, tailings dams, and stockpiles  
• Soil erosion on un-reinstated de-vegetated slopes  
• Waterlogging caused by artificial land contours and drainage patterns  
• Underground fires lead to ground slumpage and instability  |
| Socio-economic               |                                                                                                                                                                                                        |
| Legacy socioeconomic issues  | • Outstanding socioeconomic issues of coal mines and mine mouth CFPPs that have not been dealt with or mitigated before closure  |
| Regional economy             | • Early retirement of CFPPs will impact on national and international coal supply chains  
• Increased coal price  
• Reduced imports and exports, leading to imbalance in national economies  
• Infringement of international trade agreements on coal supply  
• Increased electricity and fuel prices, impacting commodity and food prices  
• Opportunities to diversify the economy that do not rely on coal  |

11.5.3 Environmental issues and impacts of closing coal mines

Coal mine closures will occur as part of the transition away from fossil fuels toward cleaner energy. They will have a range of environmental and social risks and opportunities, as described below.

Until recently, it was not common for governments to require mine decommissioning and closure. So there are many mines that have been closed poorly or abandoned and left derelict or in some cases without ownership, creating legacy issues for governments and communities.

**Greenhouse gas emissions and air quality**

Coal mining and mine closure have the potential to release coal bed methane through disturbance of the coal rock strata. Methane is released from underground mining activity through ventilation systems and degasification. Although surface mines release less methane than underground mines, the sheer volume of coal mined in surface mines allows for large volumes of methane to be released. Abandoned and closed mines release methane from diffuse vents, boreholes and fissures in the ground. Methane is a GHG with high global warming potential and can cause explosions leading to fires.

The release of methane from a mine will depend on the coal formation and the closure process, so it is difficult to quantify. Closing coal mines will have the benefit of reducing the amount of methane that would have been emitted if the coal mine had continued to operate. However, there is also a risk that in closing the operating plant, the open pit and mine shafts may continue to leak methane from the disturbed coal seam. There is potential to capture and use the methane from some larger mines. However, the small and irregular quantities of methane production from some mines makes this unviable. The volume of methane from abandoned mines around the world, although not quantified, is expected to be very high. Although the decrease in coal production would decrease methane release, it does not stop methane release altogether, and therefore, there is a need to manage methane from closed mines.

Fires may occur in abandoned mines where the methane and/or coal ignites. Such fires cause the release of airborne pollutants, which can impact the health of residents in nearby communities and cause a reduction in localized air quality. Particulate matter can also enter waterways leading to a reduction in water quality.

Coal mining can also impact on air quality due to general operational activities, e.g., dust from blasting and drilling, exhaust emissions from hauling and truck movements, and particulate matter arising from coal storage piles or the significant amounts of waste spoil generated.

Closing a coal mine and subsequent rehabilitation activities at the mine site may result in a temporary increase in trucks and machinery at the site that will cause localized air emissions from vehicle exhausts and the creation of dust. Mine closure can also lead to longer-term improvements in air quality around mining sites as a result of ceasing operational activities, and due to site rehabilitation (e.g., through revegetation), which will reduce the amount of particulate matter released to the local environment and avoid polluting waterways.

**Water quality**

Water management is one of the main environmental issues associated with an operational mine. It remains an ongoing concern when a mine is closed, when there is a need to address issues such as dewatering (pumping out water) of pits and mine shafts, coal washing, runoff and any water diversions that caused environmental impacts during operation. Many of these issues can be resolved and properly managed through effective site closure planning. In some cases, there will be a need for ongoing management and monitoring of water in pits and mine shafts.

Potential water quality impacts caused from mismanaged mining operations include acid mine drainage, algal blooms, and heavy metal pollution. These can impact nearby waterways, rendering the water unfit for human consumption and irrigation. During mine closure, a specific water management plan should be developed, and measures implemented to prevent such potential impacts, and to ensure that
stockpiles, pits and other disturbed areas are rehabilitated and revegetated to reduce the potential for contaminated runoff.

Acid mine drainage issues associated with coal are commonplace around the world, often as a result of dam failure at abandoned mines (Box 11.7). Impacts from a number of smaller abandoned mines may also have an impact.

**Box 11.7: Residual Problems of Closed Coal Mines: The case of the Sewanee Coal Seam in East Tennessee, United States**

In the Sewanee Coal Seam in East Tennessee in the United States, there are 300 abandoned coal mines. The Sewanee coal seam is surrounded by high levels of pyrite, an iron sulfide, that when exposed to water and air, creates acid mine drainage. Although these mines are no longer operational, due to this chemistry, there is no known method of preventing acid mine drainage runoff, which is highly toxic to humans, flora, and fauna, and has polluted the waterways and had impacts on communities. Although the water quality is being treated, the runoff still impacts aquatic flora and fauna and downstream users of this waterway.

*Source: Frankenberg Veal (2012)*

Subsidence during operation or closure can have an impact on streams and result in other environmental consequences. Fracturing of rockbars and dilution and cracking of bedrock can reduce the flow and water levels of streams. Subsidence may also result in soil erosion or scouring of waterways, increasing turbidity, changing water quality, and impacting on aquatic flora and fauna. These risks should be addressed through a plan for landform management and site rehabilitation.

Not only can coal mining have an impact on the quality of water but in some locations, may have an impact on surface and groundwater quantities and runoff (e.g., by blocking or diverting water courses). The reduction in volume of available water may affect nearby communities, farming, and aquatic environments. Closing of a coal mine provides an opportunity to enable surface waters to go back into water courses and groundwater systems for use by communities and to improve environmental flows.

**Noise**

Closure of coal mines will reduce the level of noise experienced by communities as equipment used for mining operations will cease operating (e.g., haulage equipment, truck movements, cutting and drilling machines, blasting, crushing, conveyors, fans, loaders, etc.). However, there may be a temporary increase in noise impacts when a mine site is being rehabilitated when trucks and machinery such as excavators will be required to operate.

**Contaminated land and groundwater**

If there is inadequate water management at abandoned or closed mines, this can result in significant pollution and contamination of surface water (Figure 11.9) or seeping into groundwater due to the discharge of mine water containing heavy metals and other pollutants. Such pollutants can be carried by rivers away from the immediate mine site and impact communities many kilometres away from the mine, polluting water used for drinking and growing food.

---

77 Johnston et al. (2008)
With the closure of a coal mine, there is the opportunity for groundwater recharge, which can have positive and negative impacts. Reducing the use of water in the mining process reduces demand on the groundwater in the vicinity of the mine and allows the groundwater source to be replenished. However, both land and groundwater can become contaminated if there are undisposed or untreated chemicals or hazardous material abandoned in the mine on closure.

The land on which mining operations occur can become highly contaminated during mining activities due to accidents and/or the careless use and storage of chemicals, fuels, and hazardous material (e.g., sulphuric acid, nitric acid and solvents, fuels and oils and heavy metals).

Remediation of the land upon closure of a mine is vital to ensure that the land can be utilized for other uses post-mining, e.g., for agriculture, grazing, or residential estates.

Untreated land and water contamination—and long-term exposure to contaminants—can lead to health impacts for people and animals. Contamination can also have an impact on soil fertility, affecting the future use of the area. However, remediating mine sites to mitigate the risks of contamination is a costly exercise and there is a risk that mining operators may simply abandon sites.

**Waste**

Waste also needs to be managed appropriately. It includes redundant infrastructure, overburden, equipment, and hazardous substances no longer required for mining that have the potential to contaminate soil groundwater and surface water.

Overburden (also called spoil or waste) is the soil and rock removed to access the coal. Open pit coal mining produces large volumes of overburden that may contain heavy metals, acid producing rock and sulphur. Overburden should be managed from the commencement of a mining operation (i.e., the vegetation should be removed, and the topsoil taken away and stockpiled separately to the overburden).

During mine closure, the environmental impact can be reduced through engineered surface water and groundwater controls, movement of overburden, reinstatement of the topsoil layer, and revegetation. During closure, the movement of the overburden has potential to expose rocks containing sulphur (a source of acid generation) and toxic metals, which may leak into the environment and impact on soils, waterways, and groundwater. This, in turn, can impact on downstream environments and lead to ecological degradation. Intake of toxic metals by humans and animals can have severe health impacts which may not show for many years.

The disposal of potential toxic overburden to areas of the mine site where contamination can be contained is recommended in areas where management on-site and rehabilitation cannot occur. Management of toxic overburden volumes within mine sites, rehabilitation, or proper disposal of surplus wastes (subject to risk, if permitted) is often a legal requirement. Planning, measures, and actions to manage overburden is routinely documented in mine site closure plans.

---

E.g. rocks containing iron sulphide minerals, such as pyrite
Land degradation

Land degradation is a key concern for coal mines due to activities such as land clearing, pit formation, underground shafts, subsidence, and erosion. It can lead to the loss of terrestrial habitats and loss of aquatic and terrestrial biodiversity, and reduced water quality. A key requirement in the successful rehabilitation of land post mine closure is to ensure that native vegetation is established over the site to stabilize the land and reduce erosion. Mine closure plans seek to restore water flow and quality to pre-mining levels and to create topography/landform that is consistent with the surrounding areas. This also aims to allow habitats to establish and biodiversity to return to previously cleared areas.

Mine closure plans are routinely prepared in consultation with the relevant government agencies, and in accordance with the relevant rehabilitation and mine closure guidelines for the local state and/or country. Mandated minimum durations for monitoring and evaluation are often required and are often varied by way of extension when site risks and the receiving environment are more sensitive.

The content of each mine closure plan reflects the land use being reinstated. For example, for rehabilitation to be successful for agriculture, drainage, revegetation, soil establishment and erosion control will be required to support this type of land use (e.g., Box 11.8).

Land use change

Land-use changes following mine closure require careful consideration and coordination to ensure that lands are repurposed, and environmental impacts are minimized and mitigated. As described above, soils and landform need to be rehabilitated to pre-mine conditions, if the former land use is to be reinstated. If the land use is to change, the extent of remediation needs to be sufficient to enable that end land use to occur. It is important for land to be rehabilitated to meet future use options in consultation with local communities.

In North America, former mines have been converted into wildlife centres, education, and research facilities, creating job opportunities in tourism and conservation (Box 11.9). Future land use may not be as complex as a wildlife centre, and rehabilitation may simply be for agriculture or grazing, or it may also make way for other industries and opportunities for new roads and water infrastructure.

11.6 Socio-economic issues and impacts of closing coal mines

Country, regional, and global economy

Coal mining is an important contributor to many national economies (Box 11.10). The closure of coal mines will affect the coal supply chain at both national and international levels, resulting in increased coal prices and reduced imports and exports. According to IRENA (2020) which analysed the global socio-economic and economic impacts of coal retirement, “An increase in imports, or reduction in exports [of coal], has a negative impact on GDP, while a decrease in imports or increase in exports has the reverse effect” 79.

79 IRENA (2020b)
Canyon Mine in New South Wales, Australia, was an open-cut coal mine and was extensively rehabilitated to pastoral land after closure in 2009 due to exhaustion of the resource. Rehabilitation included reshaping of the final void and overburden emplacements, topsoil placement, installation of water management control measures, establishment of a cover crop, planting of tube stock, and monitoring and maintenance of rehabilitated areas. The land continues to rehabilitate to pre-mining vegetation communities, including pastoral, woodland, and forest. Figure 11.10 shows the site before and after rehabilitation when an initial cover crop was established. The image also shows water retention and management post-closure. As part of the closure plan and original development approval, a water management plan documented the quarterly water monitoring data results over the 5 years post-closure (i.e., October 2010 to October 2015). At this site, largely due to the absence of contaminated materials, the results were positive, with only one discharge point requiring subsequent 6-month monitoring for a further 2 years.

Box 1.8: Rehabilitation of Canyon Mine, New South Wales, Australia

Rehabilitation former coal mines: some examples

Former East Germany was a coal mining powerhouse, but the industry collapsed after the fall of the Berlin Wall. Soon after, 25 open-pit lignite mines in the Lusatia region were transformed into recreational lakes. Spanning the states of Brandenburg and Saxony, water was fed into the former mines from several major rivers, including the Spree and Black Elster. Some 30,000 animal and plant species have since been drawn to the region, leading to an increase in biodiversity. Lake Geierswalde and Lake Partwitz in particular have since become holiday hot spots.

In West Virginia, USA, the Appalachian Botanical Company is growing lavender in the poor soils of former strip coal mines. The drought-tolerant herb is processed to produce a fragrant oil for cosmetic and culinary products. Lavender rejuvenation is labour-intensive and provides jobs for coal industry workers made redundant amid the energy transition.

Source (Braun 2013)
Box 11.10: Coal mining and economies

“Coal makes a significant economic contribution to our societies, and economies, particularly at a local level. Coal mining is still a contributor to many economies, especially in developing countries. Around 6.5 million people work in coal mining, processing and delivery. ..

Much of the coal industry in developing countries is export oriented and is a major source of foreign hard currency. Emerging economies continue to see coal as a good option for future development, but the contribution of coal is not limited to developing nations, as advanced economies benefit significantly from coal industry operations, both directly and indirectly.

In Queensland, Australia, 20,000 people were employed by the coal industry creating A$20 billion of income (2018 figures). Coal exports raised A$1 billion in royalties, providing a significant source of necessary funding for public services. Whilst in Europe, despite the significant reduction in coal production in recent years, the coal market in Germany and Poland still supports over 160,000 jobs in the form of direct and indirect employment.”

Source: https://www.worldcoal.org/

Indonesia is the second-largest coal exporter in Asia and the Pacific. In 2021, coal mining contributed 8.89% to the Indonesian GDP. The closure of coal mines would affect Indonesian economic growth. Between 1992–2009, Indonesia earned at least $9.3 billion in taxes from coal mine extraction. The Philippines imports coal from Indonesia, Australia, the PRC, and Viet Nam. Annually, the Philippines imports coal to supply its CFPPs—about 12–15 million tons of oil equivalent. Change in coal supply in Indonesia would affect international trade patterns and importing and exporting countries’ economies.

Note to reviewers: We would be grateful to have additional text (data) inserted for other countries

Closing coal mines is a politically and socially complex issue, due to the involvement of several actors from the government (particularly energy ministries), local economic development agencies, investment associations, companies, and communities. The phasing out of coal mines requires early planning, due diligence, and active social dialogue with affected stakeholders. In Indonesia, closures of mine activities are already known to create complex and severe problems, especially since many of Indonesia’s mining areas and local governments lack capacity. The sudden closure of coal mines can initially hit the local and regional economy adversely. Mass redundancies, reductions in economic output and, in more extreme cases, economic crisis, can fuel deprivation, extreme inflation and social unrest (Box 11.11).

Box 11.11: Mine Closure Conflicts in Indonesia

In Indonesia, since the 2000s, the closure of coal mines has resulted in substantial and ongoing tensions between communities, conservationists, mining companies, the Ministry of Forestry, and the Ministry of Energy and Mineral Resources. Local people receive only limited revenues, while mining operators make high profits from coal extraction. When the mineral supply is depleted, mining operators abandon the area with limited alternative revenue options for local communities. Mining operators, the government, and local communities have debated how to address this issue and the extent of environmental reclamation required prior to the closure of the mining operation. PT Kelian Equatorial Mining (KEM), one of the few mining companies in Indonesia, closed its operation in 2004. KEM had tried to implement its corporate social responsibility programs well in advance of its closure and had taken an integrated social and environmental approach to the mine.

80 Badan Pusat Statistik [Seri 2010]
81 ASEAN Today (2021)
Local economy and livelihoods

As with the retirement of CFPPs, the risks associated with coal mine closures also include negative impacts on livelihoods, employment and the well-being of local skilled workers, migrant workers, and associated businesses within the existing coal supply chains. The loss of income from jobs in coal mining would substantially reduce income flows, affecting the economy of host communities (Box 11.12). It would affect retail, accommodation services, food services, other dependent sectors, and social services. There is clear evidence that decades after coal mines have been shut down, many coal-dependent regions continue to lag socially and economically. For instance, as workers leave communities, the price of properties and of land can decline, and local government tax revenue can also decrease. It cannot be expected that renewable energy technologies will replace these revenue losses in a timely manner. Careful planning is needed when considering the shift to cleaner energy generation. Unfortunately, in many cases, this does not happen.

Box 11.12: Local economy and community dependence on coal mines

Shanxi Province in Northern People’s Republic of China provides an example of an economy dependent on the coal industry. Recent declines in the coal market and the government’s environmental commitments resulted in closures of coal mines in Shanxi in the early 2000s. This has hit the province with reduced revenues for the state-owned enterprises and tax revenue reductions for the local government. Countries in Eastern Europe such as Poland, Ukraine, and Romania had programs to restructure their coal sectors in the 1990s. These resulted in the mass closure of mines, which were often located in communities where the coal sector was a dominant source of income and economic development. Mining enterprises not only mined coal, but also provided houses and socioeconomic benefits to the workers, their communities, and towns. Communities throughout Romania, Ukraine, and Poland faced further social problems after mine closure, e.g., increased substance abuse, prostitution, and child abandonment.

Evidence from Australia shows that the emotional dimension of the mining sector and community utility associated with the coal sector can be characterized as their “cultural asset” and identity. Towns hosting coal mines are usually coal industry-driven, without many alternatives to sustain economic and social make up.

Sources: World Bank (2003); and Della Bosca and Gillespie (2018)

However, the rehabilitation of coal mining sites can create income-generation opportunities. For example, in Nord-Pas-de-Calais in northern France, former coal mines were rehabilitated to provide playgrounds, museums, hiking trails, cycling routes, artificial ski slopes, etc. Open mine pits can also be redeveloped as reservoirs or pumped-storage hydroelectricity projects, as in the state of North-Rhine Westphalia, Western Germany. Such repurposing creates economic activities for the local communities.

82 World Bank (2018b)
84 National Geographic (2022)
85 Agerholm (2017)
Many coal-dependent economies lack the incentives and resources needed to protect workers and their communities. A study of 1,000 coal mine closures from around the world between 1981 and 2009, found that 75% of all closures were unplanned.66

**Legacy of socio-economic Issues**

As with the retirement of CFPPs, closing coal mines could exacerbate prolonged unresolved (i.e., not mitigated previously by coal mine companies) socioeconomic impacts, including outstanding land conflicts, lack of compensation payments for land and property loss, lost livelihoods, and income. Such issues could be induced by the lack of enforcement of national regulations, inadequate impact assessments, and mitigation measures not following good international industrial practices (e.g., the IFC performance standards). An assessment report found that, in the Cesar department in the north of Colombia:

“There is no evidence that any activities by either [mining] company mitigated the impacts to any degree. The high degree of severity of the forced displacements continued unmitigated well into the mining companies’ timespan of operations, and those impacts remain fully unmitigated and remediated to this day”.

Such legacy issues can also be found in the Southeast Asian mining sector. Sumatra (Indonesia’s second coal-richest region) is both blessed and cursed by coal. At the beginning of 2022, the government revoked more than 2000 mining business licenses (including 1,776 mineral licenses and 302 coal licenses) because of failures to comply with requirements under national laws. The government plans to transfer the areas covered by the licenses to local entities and potential investors.89

**Health and safety**

The closure of coal mines can provide opportunities for reducing the health and associated safety risks to communities (e.g., chronic health impacts associated with coal mining, particularly underground), and for improving local water and air quality. Mine closure and land reclamation requirements should be embedded in the overall mine planning and permitting process from the outset. Good practice examples are available from Ukraine, Poland, and Romania where dedicated coal mine closure companies effectively manage the efficient and safe physical closure of mines.

A priority for mine closure needs to be the safety of people during the closure and rehabilitation phases, both within and adjacent to the mine site. Compliance with safety standards is important to protect infrastructure and prevent hazardous events and incidents from occurring.

Health and safety risks arise when a mine is not properly decommissioned. This can include land instability, subsidence, or potential water contamination from tailings dams and mine spoil areas. These risks, in conjunction with inadequate monitoring and water management, can lead to water logging, soil slumpage, slope failure and contamination within and adjacent to the closed mine site.

The closure of coal mines can benefit the health and safety of local communities. Mine closures often help improve air quality and eliminate or reduce dust at the mine site—two key public health issues associated with coal mines.

In addition, closure eliminates fatalities resulting from road accidents involving heavy vehicles transporting coal (Box11.13).

66 Strambo et al. (2019)
67 www.ifc.org
68 Wilde-Ramsing et al. (2021)
69 Zuhal (2022)
Box 11.13: Road accidents involving coal trucks in Sumatra, Indonesia

It is reported that in Sumatra, in 2022, thousands of overloaded coal trucks used the main roads each day infuriating local communities. The trucks caused traffic congestion for kilometres, and those living along the main road had no option but to breathe dust and thick diesel fumes every day. Coal truck drivers, some of them reckless, inexperienced and unlicensed, regularly caused traffic accidents with dozens of fatalities. During 2017–2019, more than 30 residents were killed, and, in 2021 alone, the number of deaths reached 34.

There may also be public health issues risks if hazardous waste is left behind in coal mine areas. Mine abandonment without remediation (filling/capping mine shafts, fencing-off, etc.) and the absence of long-term monitoring will create safety risks. For instance, animal and child drownings have been reported at abandoned mines in Australia and in Indonesia’s Borneo region (Box 11.14).

Box 11.14: Lack of post-closure remediation in abandoned coal mines in Borneo

It is reported that the owners of hundreds of abandoned coal mine pits in Borneo failed to undertake post-closure remediation, and, in some cases, it is clear that local governments did not ensure that owners complied with regulations. As a result, the surrounding communities are at risk of short- and long-term environmental and health risks.

Closed mine sites are one of the most significant pollution risks in the UK. It is important from a public health perspective to have mitigation measures in place when decommissioning. If not planned for or mitigated, heavy metals and other pollutants may be discharged into the water. According to environmental and coal authorities in the UK, some mines are filling up with groundwater and may discharge the liquid in the future, posing large-scale health and safety risks. Legislation and policy in the UK, including the Environmental Permitting Regulations (2010), National Planning Policies and the EU Mining Waste Directive (Directive 2006/21/EC) aim to protect human health. Other countries, including those in the Southeast Asia region, may lack such national regulations or may have less robust requirements that focus on health and safety when mine sites are closed.

Illegal mining

In countries where regulatory enforcement is weak due to inadequate institutional support, coal mining may be carried out by illegal and unlicensed companies or individuals. Such illegal mines are reported in many low-income countries, both small- and large-scale90 91 and can have significant consequences (Box 11.15).

Coal mine closure can increase pressure on the capacity of local and central governments to manage the remaining coal resources. For many reasons, government capacity may be limited by insufficient public budget allocations by the central government. In such situations, opportunistic mining (individuals or entities) may find loopholes to extract coal illegally.

Employment and labour conditions

Phasing out coal mining is a complex process and will affect local workers. This is particularly true for regions highly dependent on coal-related activities. It is expected that the direct decline in coal-related jobs seen over the past decade will continue, largely driven by the environmental agreements and transformation into alternative renewable energy resources. According to the International Energy Agency (IEA), by 2030, 30% fewer people are expected to work in coal-related sectors compared to 2019. Almost a third of this decline is expected in coal mining. According to the World Bank, the closure of coal mines can exacerbate the existing socio-economic and employment impacts, given the geographic isolation, disparity in wages and the distinct culture of coal mining towns. These factors are expected to pose further challenges to the recovery efforts regarding employment and labour conditions.

Employment in coal mines varies from one site to another due to the size and accessibility of the coal deposit. However, coal mining sites tend to employ more workers than CFPPs. The closure of coal mines tends to create significant adverse job loss impacts. In Poland, efforts to close coal mines reduced jobs drastically from around 390,000 in 1989 to about 150,000 workers in 1999 (Figure 12).

Box 11.15: The consequences of illegal coal mining in Indonesia

Following the Asian financial crisis and unemployment in Indonesia, illegal coal mining activities significantly increased from 1998 onwards. Further expansion of such illegal mining was also fuelled by the decentralization of the coal sector aimed at boosting the economy and energy supply. Lenient sanctions and corruption in granting mining permits resulted in inconsistencies in mining regulation and policies, which led to local resistance to the government. The Government of Indonesia used to tackle only symptomatic cases of illegal mining activity. This led to illegal and complex networks of coal mining operations increasingly funded and backed by foreign investors to avoid tax and other regulatory commitments. As a result, businesses in neighbouring countries and overseas used Indonesia’s illegal mining sector without having to internalize and address deep socioeconomic and environmental externalities and repercussions.

Although illegal mining temporarily supported local and regional economic development, it also resulted in long-term and deep inter-communal conflict and social unrest. For example, in Pongkor region (West Java), the opportunities to engage in illegal mining led to the development of rebel groups and increased fighting over mining territories.

Large companies’ mining operations and extraction activities in the region resulted in continued violence and an increase in sex-workers, child labour, and fatal occupational accidents.

In Indonesia, workers were killed at illegal mining sites due to improper health and safety measures (Figure 11.11). In 2006, illegal mining sites in Kalimantan were found to involve child labour with about 10% of workers reported as being under 17 years old. In Sumatra, non-transparent coal mining concessions increased rapidly from 750 in 2001 to 10,900 in 2022. Over 1,000 of these mining permits were revoked by President Joko Widodo because the mining had harmed both social fabric and environment of the communities. Such situations could worsen when the state’s budget allocation for managing the coal mining resources diminishes as the need for coal for coal-fired power plants gradually declines.

According to the Indonesian Bureau of Statistics, the mining and extraction industry employed 1,443,422 Indonesians in August 2021. If the coal mines close, many workers will be affected. As such, community protests closures can be expected in areas neighbouring mines. This will be particularly important when announcing how the energy transition will occur in areas facing coal mine closure or CFPP retirement.

Coal mine work is characterized by the International Labour Organisation (ILO) as difficult, dangerous, and rarely associated with good labour relations\(^97\). There is plenty of evidence of coal mines operating without proper health and safety standard. In Sumatra, up to 34 residents were killed by road accidents caused by a coal mine transportation truck\(^98\). As with retiring CFPPs, the process of closing mines could reduce or eliminate the use of forced labour, child labour and/or subject to substandard working conditions through introducing or changing existing laws to make such practices illegal, and by ensuring systems are in place to enforce laws and regulations. Lending and financing institutions (e.g., the MDBs) could make such practices unacceptable through imposing lending requirements for safeguard implementation.

There are opportunities that some or all workers who lose jobs in coal mines could be retrained and upskilled for job placement programs, and to pursue employment opportunities in renewable energy projects or other sectors. For instance, evidence from job placement programs in the UK and Canada (both coal-exiting economies) shows that opportunities for former miners were largely limited to part-time and short-term positions, which did not replace the long-term security and benefits provided by full-time coal mining jobs. Part-time workers generally receive low wages, have limited advancement opportunities and unpredictable working hours, lack of pension contributions, and face undesirable working and living conditions, all limiting their career prospects\(^99\).

Indigenous communities

When coal mines close, adjacent indigenous communities face similar issues to those highlighted during CFPP retirement (Chapter 6). However, when coal mines are to shut down, the indigenous communities can face both challenges and opportunities. Challenges include difficulties to assert their rights to reclaim natural resources, cultural sites, and places to practice cultural traditions, and their ability to participate in redevelopment projects. Indigenous communities, or specific groups within them, are often already considered to be vulnerable. Where indigenous communities rely on coal mines for their livelihoods, the closure of such mines can increase their vulnerability and force them further into poverty.

Energy transition involving coal mine closure can cause unintended and complex social challenges, universally overlooked in policy making. Many cases of coal mine closure in the southwestern regions of the US demonstrate these challenges. As mentioned in Chapter 6, there are many Native American peoples’ lands in the US with large coal reserves exploited by mining. Indigenous communities occupying these lands are therefore disproportionately impacted as host communities. In the face of mine closures, indigenous communities will need to agree how they want the land reclaimed, considering that their past, current, and future identity are closely aligned with the physical, cultural, and spiritual representation of the land.

There are also several benefits to indigenous communities from coal mine closure, not least a transition to cleaner energy sources that can offset negative environmental and health conditions. Closure may create an opportunity for such communities to reclaim land, natural resources and revive their customary land-use practices and culture, as in East Kalimantan, Indonesia.

Gender and vulnerability

As with CFPP retirement, the social risks and issues associated with mine closure, particularly those related to employment, livelihoods, and well-being, are felt differently by women and men, challenging and changing gender roles, relations and identities (Box). Mine closure can compound social inequalities faced by women and the most vulnerable, particularly those from protected characteristic groups such as indigenous peoples).

Box 11.16: Gender difference in employment in coal mines in Kalimantan, Indonesia

For the indigenous peoples of Kalimantan in Indonesia, coal extraction predominantly offers income for men of the region, while women search for more precarious (and possibly informal) work. The coal industry here serves to solidify gendered divisions of labour, with the closure of the industry likely to expose such vulnerabilities further.

Source: Lahiri-Dutt (2012)

The risks and issues associated with gender and vulnerable groups highlighted in section 11.5.2 subsection on gender and vulnerability) apply equally to coal mine closure, and include:

- Greater financial and domestic burdens placed on women resulting from sudden job losses;
- A shift in traditional gender roles - heightening instances of intra-household tension, sexual and gender-based violence and psychological distress.

Migration

Mine closure can cause unintended and complex social challenges such as migration, which is universally overlooked in policy making. Out-migration of the mining labour force (particularly skilled

100 IFC (2012b)
101 University of New Mexico (2017)
102 The Asia Foundation (2016)
103 Mayer (2021)
workers) can lead to significant demographic change. Evidence shows that extended out-migration can also put a strain on local businesses, tax revenues and the associated delivery of public services, as experienced in Yorkshire and Wales, UK\textsuperscript{104}.

Depending on the size of the coal mine, out-migration can be small or large. In most cases, the closure of coal mines can cause large-scale out-migration, especially from mining areas that operate for years or decades. Over time, skilled workers become a significant local resource for the communities in the mining area and, when they leave, this creates a skills vacuum. Similarly, those who had settled in the mining areas to work in small businesses associated with the mining activities may leave for other opportunities.

Opportunities may also arise when coal mines are closed early. These could be created by requirements of financing organizations that coal mine companies compensate workers affected by mine closure and provide a programme for reskilling and upskilling workers so that they can pursue job opportunities in renewable energy and other sectors. However, such reskilling will not occur quickly and must be adequately planned for.

**Public services and infrastructure**

As for the early retirement of CFPPs, the closure of coal mines can affect public services and infrastructure such as transportation, and health and education facilities in areas where the mining companies are present and where they have large corporate responsibility budgets. The ability of local governments to spend tax revenues on maintaining public facilities may also be reduced.

Indonesia is Southeast Asia’s largest exporter of coal, supplying many neighbouring countries. In the coming years, it could face the same experience as Yorkshire and South Wales in the UK, where mine closures created social tensions due to the loss of community services such as hospitals and schools. Local communities are often dependent on services provided or financed by mines (e.g., literacy, and health and education services). Problems arise when these cease or are no longer funded as a casualty of mine closure\textsuperscript{105}. In Southeast Asia, especially in the Philippines and Indonesia, the closing of mine activities can create more complex problems than in higher-income countries.

The existence of mining projects in Indonesia has often been regarded as a catalyst for accelerating development of infrastructure and increasing community well-being in many areas. This is particularly true for many districts (Kabupaten) where local governments generally lack the capacity to provide public services\textsuperscript{106}.

Section 11.4.2 discusses how communities may become dependent on public services and infrastructure provided and/or financed by CFPPs and coal mines (e.g., in Betul District, Madhya Pradesh, India\textsuperscript{107}, see Box11.7). However, the lack of financial support from mining companies could be offset by the reduced pressure on the public services and infrastructure due to out-migration; and even by the reduction of heavy vehicle movements which would then require less public expenditure on road infrastructure repair and rehabilitation.

**Community cohesion and engagement**

The social risk posed by rapid coal mine closures, compounded by the variations in coal mine ownership, points to the important leadership and communication roles required of governments to plan and prepare for such closures. Those planning coal mine closure must consider how best to mitigate impacts on people and communities.

Avoidance of conflict and protests is a critical measure of success in coal mine closure programs as successfully demonstrated by several coal sector reform programs in Poland and Romania (Box11.17).

\textsuperscript{107} Gupta (2021)
Box 11.17: Engagement with coal mine workers and communities over mine closure

Extensive dialogue channels were established with trade unions in Poland, facilitating a mechanism for reform acceptance and implementation, supported by the continued engagement with mine workers.

In Romania, community representatives were involved in capacity building and identifying direct employment opportunities as part of the coal mine decommissioning process, and discussions on the repurposing of infrastructure and other assets, which guided realistic expectations. This engagement with mine workers and community representatives not only contributed to the acceptance of mine closures but also contributed greatly to the design of social and labor support measures for workers, their families, and communities.

In Ukraine and the United Kingdom, there was a lack of significant stakeholder engagement with regard to closure of coal-fired power plants and mines. In Ukraine, reforms were blocked. In the United Kingdom, reforms were achieved but there were protracted conflicts with unions and mine workers over a two-decade period after 1984.
